Deployment Guide

Typical deployment flow: prepare environment → configure environment variables → install dependencies → build application → configure database and services → deploy → verify → monitor.

Deployment Checklist

Confirm environment configuration, dependencies, database connectivity, API credentials, access permissions, build status, logs, domain configuration, and deployment health.

API Documentation

API documentation should define authentication, base URL, endpoints, HTTP methods, parameters, request/response formats, status codes, rate limits, and error handling. Production credentials should never be stored in public documentation.

Integration Guide

Identify the external system → review API documentation → obtain credentials → define data mapping → implement authentication → test sandbox → handle errors → production rollout → monitor.

Troubleshooting Guide

Reproduce the issue, check logs, confirm configuration and environment variables, test dependencies, verify network/API status, and review recent changes.

Technical Escalation

When an issue persists, collect timestamps, error messages, logs, reproduction steps, environment details, and recent changes before escalating.
